What about contamination?

This study is often misquoted as it found higher than normal levels of lead in honey bees.....but not the honey.

“Honey collected from hives across Sydney contained negligible amounts of lead and didn’t exceed a concentration of 22 μg/kg. However, the amount of lead found in the honey of Broken Hill city bees, which had an average concentration of 295 μg/kg, was more than ten times the maximum of the bees measured in Sydney,” said Professor Taylor.
